

IV Calculations

First step

INFUSION FLUID			INFUSION DURATION or RATE	MEDICINE ADD
TYPE/STRENGTH	VOLUME	ROUTE		APPROVE NAME
Sodium Chloride 0.9%	1000 mL	I.V.	8 hours	

- **Think:** Driving speeds are *miles per hour*.
Infusion speed is *mL per hour* (mL/hr).

- Enter onto calculation:

$$\frac{1000 \text{ mL}}{8 \text{ hour(s)}} = 125 \text{ mL/hr}$$

- Use the machine as a clue for where to put each number:

Next step

How to remember DRD?

Think of a clock – how many “drops around the clock”?

- From the I.V. Administration Set, **20 drops/mL** → **DRD: 3**:

- In this example, $125 \div 3 = 41.666\dots$ so we round up to 42.
- Set this on the IV:

Extended method

Correct layout of extended method:

$$\frac{1000 \text{ mL}}{8 \text{ hour(s)}} \times \frac{20 \text{ drops / mL}}{60 \text{ min / hr}} = 42 \text{ drops / min}$$

- The first part ($1000 \div 8$) is the same as before.
- This time, put the drops per mL and 60 min / hr (there are always 60 minutes in an hour!)

How to solve? Shortcut – carry on using DRD!

- The first part is $1000 \div 8$, which is 125 (calculated on the previous page).
- Next step in calculation is to multiply by $\frac{20}{60}$. BUT if you divide by the DRD (i.e. 3), you will get the same answer in fewer steps.
